

Luby's Algorithm for finding Maximal Independent Set

15418 Final Project - Spring 2022

Clarissa Xu and Arvind Mahankali

5th May, 2022

Agenda

- Background
- Luby's Algorithm Overview
- What We Did
- Our Earlier Approaches
- Our Approach
- Runtimes and Speedup

Background

- Input: Graph $G = (V, E)$ in adjacency list representation
- Output: Maximal Independent Set
 - A set S of vertices in G such that there is no edge in G between any 2 vertices in S , and for any vertex v not in S , there is an edge from some vertex in S to v .

Luby's Algorithm

1. Determine if there are any vertices left in the active set A
2. Assign random priorities to all of the vertices in the active set
3. For each vertex v in A , go through the priorities of all neighbors and find the max of those. Compare this to v 's priority and determine if v should be added to the independent set
4. Update the independent set and remove the newly added vertices from the active set

What we did

- Greedy sequential algorithm
- Sequential version of Luby's algorithm
- 3 parallel programs with MPI
- 1 program to generate random undirected graphs for testing
- 1 checker python program to check if outputted a valid maximal independent set

V1: Initial Luby's

- Root determines all the priorities and all the active sets and broadcasts them
- Each process determines which of their vertices are in the independent set

V1: Runtimes and Speedup

V2: Luby's with Blocked Assignment

- Each process calculates priorities for their vertices
- Each process sends the priority of a vertex to each of their neighbors
 - Synchronous Send and Receive Calls
- Each process p sends a message to every other process q containing neighbors of vertices in q that are no longer in the active set

V2: Runtimes and Speedup

Blocked Assignment Luby's Algorithm Runtime for $n = 15$, $E = 100,000$

Blocked Assignment Luby's Algorithm Speedup for $n = 15$, $E = 100,000$

V3: Luby's with Blocked Assignment and Single Messaging

- We collate communication to send all pertinent priority and active set neighbor information in one message to each process, rather than by edge
- We observe that a process p does not have to exchange messages with process q if they don't have edges between active vertices

Adjacency list

- 0: [1, 2, 3, 5, 7]
- 1: [0]
- 2: [0, 4, 6]
- 3: [0, 6, 7]
- 4: [2, 5]
- 5: [0, 4]
- 6: [2, 3]
- 7: [0, 3]

Sending of Priorities

	Proc 0	Proc 1	Proc 2	Proc 3
Who it needs to comm	1, 2, 3	0, 1, 3	0, 1	0, 1
t=0	exchange w/ 1	exchange w/ 0	waiting for 0	waiting for 0
t=1	exchange w/ 2	waiting for 2	exchange w/ 0	waiting for 0
t=2	exchange w/ 3	exchange w/ 2	exchange w/ 1	exchange w/ 0
t=3	DONE	exchange w/ 3	DONE	exchange w/ 1

Gen Priorities

active Nodes Priority

Proc0 [0 → P₀] 1: {P₀ → 2, P₀ → 3}
 [1 → P₁] 2: {P₀ → 5}
 3: {P₀ → 7}

Proc1 [2 → P₂] 0: {P₂ → 0, P₃ → 0}
 [3 → P₃] 2: {P₂ → 4}
 3: {P₂ → 6, P₃ → 6, P₃ → 7}

Proc2 [4 → P₄] 0: {P₃ → 0}
 [5 → P₅] 1: {P₄ → 2}

Proc3 [6 → P₆] 0: {P₁ → 0}
 [7 → P₇] 1: {P₆ → 2, P₆ → 3, P₇ → 3}

Determining new independent set

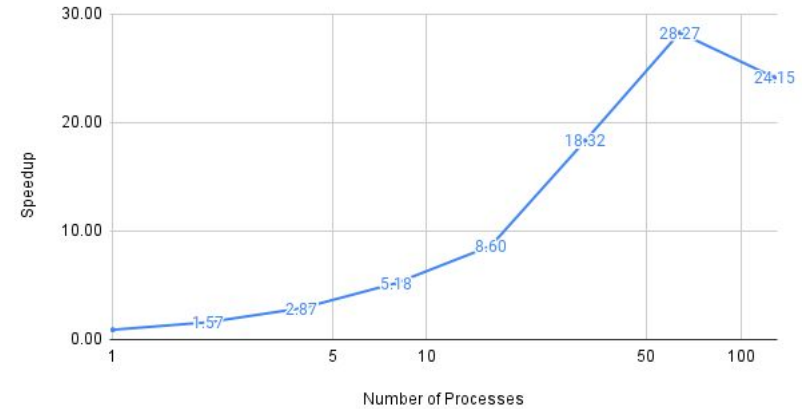

V3: Runtimes and Speedup

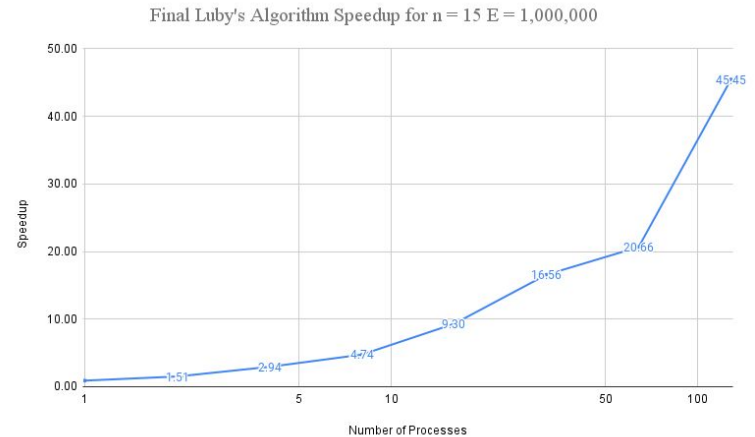

Final Luby's Algorithm Runtimes for $n = 15$ $E = 100,000$

Final Luby's Algorithm Speedup for $n = 15$ $E = 100,000$

V3: Runtimes and Speedup
